Tutorial 1: Agents, Problems, and Uninformed Search (Solutions)

1. Sudoku is a popular number puzzle that works as follows: we are given a 9×9 square grid; some squares have numbers, while some are blank. Our objective is to fill in the blanks with numbers from 1 – 9 such that each row, column and the highlighted 3×3 squares contain no duplicate entries (see Figure 1).

Sudoku puzzles can be solved easily after being modelled as a CSP (which we will cover later in the module). We will consider the problem of *generating* Sudoku puzzles.

One possible procedure for doing this is to start with a completely full number grid (see Figure 2), and iteratively make some squares blank. We continue blanking out squares as long as the resulting puzzle can be completed in only one way.

- (a) Determine the properties of the above problem from the perspective of an intelligent agent planning a solution. Complete the table below.

Solution: The completed table is as follows.

	Environment Characteristic	Sudoku Puzzle
1	Fully vs Partially Observable	Fully
2	Deterministic vs Stochastic	Deterministic
3	Episodic vs Sequential	Episodic or Sequential *
4	Discrete vs Continuous	Discrete
5	Single vs Multi-Agent	Single
6	Static vs Dynamic	Static

* Note that a typical human player who attempts to solve a Sudoku puzzle would perceive the problem environment as sequential, since each move they made would be seen to impact future moves.

However, an intelligent agent solving the Sudoku might not. To such an agent, the problem might seem episodic since it would be able to plan all the moves ahead of making any. To such an agent, the Sudoku puzzle solved by utilising an internal model

to simulate and solve the puzzle. Once the plan is devised, a single action is taken to input all the correct values. Solving the problem is episodic.

Ultimately, the definition of the properties of a problem environment are contingent upon an interpretation of the agent's use cases.

(b) Define the search space for the problem of generating a Sudoku Puzzle by completing the following.

- Give the representation of a state in this problem.
- Using the state representation defined above, specify the initial state and goal state(s).
- Define its actions.
- Using the state representation and actions defined above, specify the transition function T . (In other words, when each of the actions defined above is applied to a current state, what is the resulting state?).

2	5			3		9		1
	1				4			
4		7				2		8
		5	2					
				9	8	1		
	4				3			
			3	6			7	2
	7							3
9		3				6		4

Figure 1: A simple Sudoku Puzzle

Solution:

- A state in this problem is a (partial) valid solution of the sudoku puzzle. More formally, it would be a matrix $A \in \{0, \dots, 9\}^{9 \times 9}$ with 0 representing a blank square.
- The initial state is a completely filled out grid of numbers, where the grid is valid: all rows, columns and 3×3 squares contain all numbers between $1, \dots, 9$. Note that any state in the problem will be a valid goal state.

- An action would be removing a number from the grid. More formally, we take as input a matrix A and a matrix $E_{i,j}(a)$ where $E_{i,j}(a) \in \{0, \dots, 9\}^{9 \times 9}$ is a matrix of all zeros except for a non-zero value $a \in \{1, \dots, 9\}$ at coordinate (i, j) . An action would be setting $A - E_{i,j}(a)$. Note that actions must not result in boards with two or more solutions.
- The transition model would be $T(A, E_{i,j}(a)) = A - E_{i,j}(a)$.

It is worthwhile to think about how you would make a good puzzle generator. It would probably make sense to randomly remove numbers rather than deterministically doing so. There are many goal nodes here, but it would probably be boring to use your Sudoku generator if its output was always the same puzzle given the same input.

2	5	8	7	3	6	9	4	1
6	1	9	8	2	4	3	5	7
4	3	7	9	1	5	2	6	8
3	9	5	2	7	1	4	8	6
7	6	2	4	9	8	1	3	5
8	4	1	6	5	3	7	2	9
1	8	4	3	6	9	5	7	2
5	7	6	1	4	2	8	9	3
9	2	3	5	8	7	6	1	4

Figure 2: Solution to the Sudoku puzzle in Figure 1.

- (a) Describe the difference between **Tree Search** and **Graph Search** algorithms.

Solution: Graph search algorithms will not explore redundant paths – i.e., they only explore nodes (i) with associated states that have not been visited, or (ii) have been visited, but previously via less optimal paths. Tree-based algorithms have no such restriction; they consider all paths, including redundant ones.

- (b) Assuming that ties (when pushing to the frontier) are broken based on alphabetical order, specify the order of the nodes checked (i.e., via the goal test) by the following algorithms. Assume that S is the initial state, while G is the goal state.

You should express your answer in the form $S-B-A-F-G$ (i.e., no spaces, all uppercase letters, delimited by the dash (-) character), which, for example, corresponds to the order S , B , A , F , and G .

Figure 3: Graph for Question 2b.

- i. Depth-First Search with tree-based implementation
- ii. Depth-First Search with graph-based implementation
- iii. Breadth-First Search with tree-based implementation
- iv. Breadth-First Search with graph-based implementation

Solution:

- i. $S-C-E-D-B-E-D-D-A-F-G$
- ii. $S-C-E-D-B-A-F-G$
- iii. $S-B-C-A-D-E-E-F-D-D-G$
- iv. $S-B-C-A-D-E-F-G$

Do note that this is an academic exercise. We typically only use a graph-implementation with BFS and a tree-implementation with DFS.

3. Prove that the **Uniform-Cost Search** algorithm is optimal as long as each action cost exceeds some small positive constant ϵ .

Solution: Given that each action cost exceeds some small positive constant ϵ , completeness may be assumed. Consequently:

- Whenever UCS expands a node n , the optimal path to that node has been found. If this was not the case (i.e., the path to n was not optimal - let us denote this path T), there would have to be another frontier node n' on the optimal path from the start node to n (denote this optimal path U). By definition, $g(n)$ via U would be less than $g(n)$ via T , which implies that n' should have been selected first.
- If action costs are nonnegative, path costs, i.e., g values never get smaller as nodes are added.

The above two points together imply that UCS expands nodes in the order of the optimal path cost.

4. You are given an n -piece unassembled jigsaw puzzle set (you may assume that each jigsaw piece can be properly connected to either 2, 3, or 4 pieces), which assembles into an $(m \times k)$ rectangle (i.e., $n = m \times k$). There may be multiple valid final configurations of the puzzle. Figure 4 illustrates an example.

Figure 4: A sample configuration of the jigsaw puzzle.

Formulate the above as a search problem. More specifically, define the following:

- State representation

- Initial state
- Actions
- Transition model
- Step cost
- Goal test

If necessary, you may identify the assumptions you have made. However, assumptions that are contradictory to any instruction in the question, or that are unreasonable, will be invalid.

Solution:

- State representation:
 - Keeps track of the connections (i.e., 2/3/4 per piece) across all the puzzle pieces.
 - Maintain either the set of connected connections or unconnected connections.
- Initial state:
 - Depending on the representation, either the set of connected puzzle pieces is empty, or the set of unconnected puzzle pieces is full. There should also be no connections between puzzle pieces initially.
- Actions:
 - Taking two unconnected puzzle pieces and establishing a connection between them. Note that you must mention that the pair of puzzle pieces picked can be legally connected (i.e., you cannot simply take *any two* puzzle pieces).
- Transition model:
 - Depending on the representation, can either add to the connected set or remove from the unconnected set.
- Step cost
 - Step costs are 1 (or any positive constant value; cannot be 0).
- Goal test
 - Depending on the representation, either the connected set is full, or the unconnected set is empty.
 - Check that for every puzzle piece, there should not be more connections than its number of available legal connections.

5. You have just moved to a strange new city, and you are trying to learn your way around. Most importantly, you want to learn how to get from your home at S to the MRT station at G .

Figure 5: Graphical representation of the city.

Apply the **Depth-First Search** algorithm with **tree-based implementation**. Use alphabetical order to break ties when deciding the priority for pushing nodes into the frontier.

Determine the final path found from the start (S) to the goal (G). Note that you **MUST** express your answer in the form $S-B-C-J-L-G$ (i.e., no spaces, all uppercase letters, delimited by the dash (—) character), which, for example, corresponds to the exploration order of S , B , C , J , L , then G .

Solution: $S-B-F-H-D-G$
